Lab 4

Autumn Li and UNI ql2280 October 29, 2016

Instructions

We'd like you to knit this lab as a .pdf file today. From now on, we'll hand in homeworks as .pdfs so we'll use lab today as an opportunity to practice this. Include output for each question in its own individual code chunk and don't print out any vector that has more than 20 elements.

Objectives: Importing and manipulating data; writing functions to estimate parameters; writing functions to check model fit.

Background

On the exam we looked at a dataset containing information on America's richest people. In this lab we continue to look at the very rich by turning to a more systematic data source than Forbes magazine, the World Top Incomes Database (WTID) hosted by the Paris School of Economics [http://topincomes.g-mond.parisschoolofeconomics.eu]. This is derived from income tax reports, and compiles information about the very highest incomes in various countries over time, trying as hard as possible to produce numbers that are comparable across time and space. For most countries in most time periods, the upper end of the income distribution roughly follows a Pareto distribution, with probability density function

$$f(x) = \frac{(a-1)}{x_{min}} \left(\frac{x}{x_{min}}\right)^{-a}$$

for incomes $X \ge x_{min}$. (Typically, x_{min} is large enough that only the richest 3%-4% of the population falls above it.) As the *Pareto exponent*, a, gets smaller, the distribution of income becomes more unequal, that is, more of the population's total income is concentrated among the very richest people.

The proportion of people whose income is at least x_{min} whose income is also at or above any level $w \ge x_{min}$ is thus

$$\mathbf{Pr}(X \ge w) = \int_w^\infty f(x) dx = \int_w^\infty \frac{(a-1)}{x_{min}} \left(\frac{x}{x_{min}}\right)^{-a} dx = \left(\frac{w}{x_{min}}\right)^{-a+1}.$$

We will use this to estimate how income inequality changed in the US over the last hundred years or so. (Whether the trends are good or bad or a mix is beyond our scope here.) WTID exports its data sets as .xlsx spreadsheets. For this lab session, we have extracted the relevant data and saved it as wtid-report.csv.

Part 1

1. Open the file and make a new variable containing only the year, "P99", "P99.5" and "P99.9" variables; these are the income levels which put someone at the 99th, 99.5th, and 99.9th, percentile of income. What was P99 in 1972? P99.5 in 1942? P99.9 in 1922? You must identify these using your code rather than looking up the values manually. (You may want to modify the column names to make some of them shorter.)

```
wtid.report <- read.csv("~/Desktop/wtid-report.csv", header=FALSE)
year = wtid.report$V2
P99 = wtid.report$V3
P99.5 = wtid.report$V4
P99.9 = wtid.report$V5
P1972 = P99[year == 1972];P1972

## [1] 215836.27
## 104 Levels: 103958.29 105979.79 106563.74 106592.26 106718.27 ... P99 income threshold
P1942 = P99.5[year == 1942];P1942

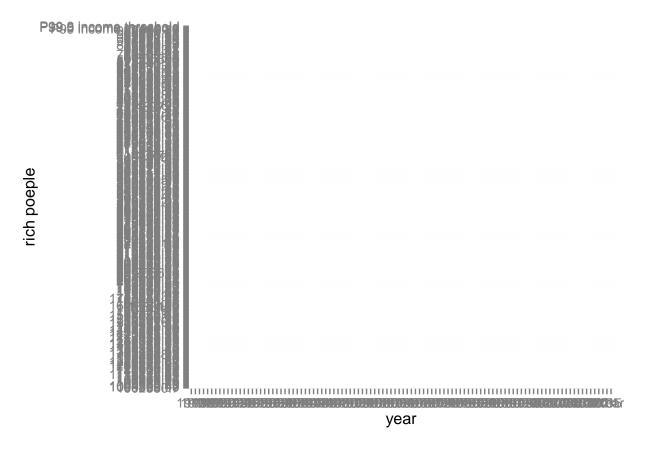

## [1] 189140.57
## 104 Levels: 112626.51 115722.66 122555.68 126224.34 126910.52 ... P99.5 income threshold
p1922 = P99.9[year == 1922];p1922

## [1] 413153.49
## 104 Levels: 1002380.7 1003303.99 1004560.48 1134215.47 ... P99.9 income threshold</pre>
```

2. Plot the three percentile levels against time using ggplot. Make sure the axes are labeled appropriately, and in particular that the horizontal axis is labeled with years between 1913 and 2012, not just numbers from 1 to 100. Remember library(ggplot2). In my plot I used multiple layers of geom_line and didn't include a lengend (but plotted the years in different colors).

```
library("ggplot2", lib.loc="/Library/Frameworks/R.framework/Versions/3.0/Resources/library")
ggplot(data = wtid.report) +
  geom_line(mapping = aes(x=year,y=P99))+
  geom_line(mapping = aes(x=year,y=P99.5),color = "blue")+
  geom_line(mapping = aes(x=year,y=P99.9),color="red")+
labs(main = "Rich time through time",x = "year",y="rich poeple")
```

geom_path: Each group consist of only one observation. Do you need to adjust the group aesthetic? ## geom_path: Each group consist of only one observation. Do you need to adjust the group aesthetic? ## geom_path: Each group consist of only one observation. Do you need to adjust the group aesthetic?

3. One can show from the earlier equations that one can estimate the exponent by the formula

$$a = 1 - \frac{\log 10}{\log\left(\frac{P99}{P99.9}\right)}\tag{1}$$

Write a function, exponent.est_ratio() which takes in values for P99 and P99.9, and returns the value of a implied by (1). Check that if P99=1e6 and P99.9=1e7, your function returns an a of 2.

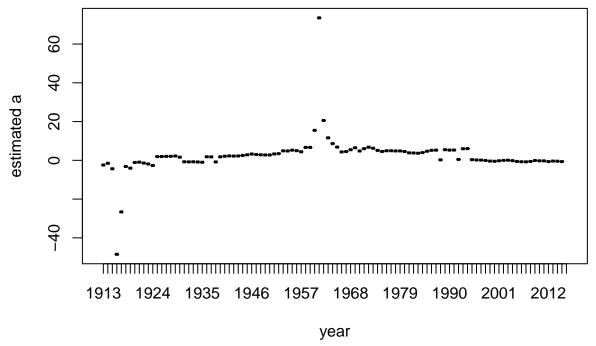

```
P99 = wtid.report$V3
P99.5 = wtid.report$V4
P99.9 = wtid.report$V5
exponent.est_ratio = function(P99,P99.9){
   a = 1-log(10)/log(as.numeric(P99)/as.numeric(P99.9))
   return(a)
   }
exponent.est_ratio(P99=1e6,P99.9=1e7)
```

[1] 2

Part 2

4. Estimate a for each year in the data set, using your exponent.est_ratio() function. If the function was written properly, you should not need to use a loop. Plot your estimate of a over time using ggplot. Do the results look reasonable? (Remember that smaller exponents mean more income inequality.)

```
P99 = wtid.report$V3
P99.5 = wtid.report$V4
P99.9 = wtid.report$V5
exponent.est_ratio(P99,P99.9)

```

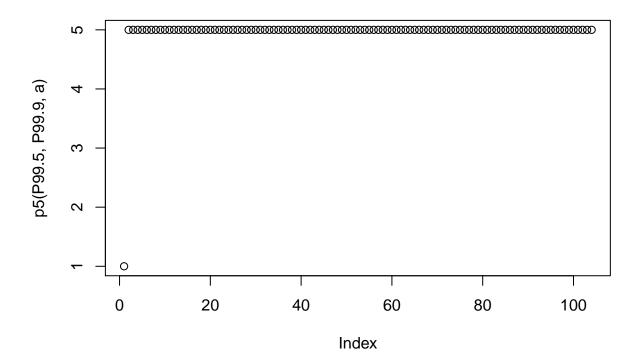

The logic leading to (1) also implies that

plot(p5(P99.5,P99.9,a))

$$\left(\frac{P99.5}{P99.9}\right)^{-a+1} = 5$$

5.

Write a function which takes P99.5, P99.9, and a, and calculates the left-hand side of that equation. Plot the values for each year using ggplot, using the data and your estimates of the exponent. Add a horizontal line with vertical coordinate 5. How good is the fit?

6. By parallel reasoning, we should have $(P99/P99.5)^{-a+1} = 2$. Repeat the previous step with this formula. How would you describe this fit compared to the previous ones?

(Note: the formula in (1) is not the best way to estimate a, but it is one of the simplest.)
